

Exercise 8

Consider the diffusion equation on $(0, l)$ with the Robin boundary conditions $u_x(0, t) - a_0 u(0, t) = 0$ and $u_x(l, t) + a_l u(l, t) = 0$. If $a_0 > 0$ and $a_l > 0$, use the energy method to show that the endpoints contribute to the decrease of $\int_0^l u^2(x, t) dx$. (This is interpreted to mean that part of the “energy” is lost at the boundary, so we call the boundary conditions “*radiating*” or “*dissipative*.”)
